Regression

$$Y_i \stackrel{ind}{\sim} N(\mu_i(\mathbf{X}_i), \sigma)$$
 where $E[Y_i] = \mu_i(\mathbf{X}_i)$

$$\mu_i(\mathbf{X}_i) = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \dots + \beta_p X_{pi}$$
$$= \mathbf{\beta}^T \mathbf{X}_i$$

Logistic Regression

$$Y_i \stackrel{ind}{\sim} \text{Bernoulli}(\pi_i(\mathbf{X}_i))$$
 where $E[Y_i] = \pi_i(\mathbf{X}_i)$

$$logit(\pi_i(\mathbf{X}_i)) = \log\left(\frac{\pi_i(\mathbf{X}_i)}{1 - \pi_i(\mathbf{X}_i)}\right) = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \dots + \beta_p X_{pi}$$
$$= \mathbf{\beta}^T \mathbf{X}_i$$

Estimation

$$\underset{\beta}{\operatorname{argmin}} L[\tau(\theta), T(X)] \Leftrightarrow \underset{\beta}{\operatorname{argmax}} L(\beta, \sigma)$$

- Regression → SSE
- Logistic Regression → Cross Entropy

Cross Entropy

$$CE_i = -\sum_{k=1}^{C} y_{ik} \log \pi_i(k)$$

 y_{ik} : the k^{th} value in y_i

 $\pi_i(k)$: the probability for the i^{th} observation to belonging to Class k

For C = 3 (number of Class)

Class 1: $y_i = (1,0,0)$ Class 2: $y_i = (0,1,0)$

Class 3: $y_i = (0,0,1)$

⇒ One-Hot encoding

$$\sum_{i=1}^{n} CE_i = -\sum_{k=1}^{C} \left[y_{i1} \log \pi_i(1) + y_{i2} \log \pi_i(2) + y_{i3} \log \pi_i(3) \right]$$

• IF Class 2,

Class 1:
$$y_i = (1,0,0)$$
 Class 2: $y_i = (0,1,0)$ Class 3: $y_i = (0,0,1)$
$$CE_i = -[\mathbf{0} * \log \pi_i(1) + \mathbf{1} * \log \pi_i(2) + \mathbf{0} * \log \pi_i(3)]$$
$$= -\log \pi_i(2)$$
$$\Rightarrow \text{IF } \pi_i(2) = 1, \text{ then } CE_i = -\log 1 = 0 \text{ (minimum Loss)}$$

Categorical Cross Entropy

$$CE_i = -\sum_{k=1}^C y_{ik} \log \pi_i(k)$$

Likelihood of ?

$$Y_i \stackrel{ind}{\sim} Multi(\pi_1, \cdots, \pi_k)$$

■ For C = 2 (number of Class)

$$P(Y_i = 1 | \mathbf{X}_i) = \pi_i(\mathbf{X}_i) = \frac{e^{\boldsymbol{\beta}^T \mathbf{X}_i}}{1 + e^{\boldsymbol{\beta}^T \mathbf{X}_i}} = \frac{1}{1 + e^{-\boldsymbol{\beta}^T \mathbf{X}_i}}$$
 (sigmoid function)

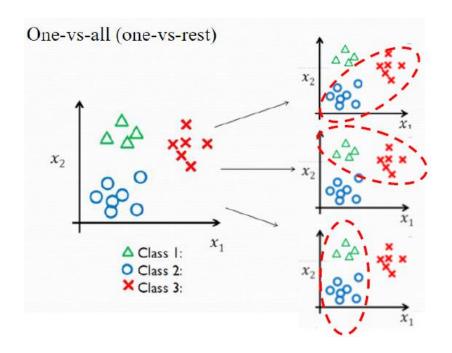

For C = 2 (number of Class)

$$P(Y = 1 | \mathbf{X}_i) = \pi(\mathbf{X}_i) = \frac{e^{\beta^T \mathbf{X}_i}}{1 + e^{\beta^T \mathbf{X}_i}} = \frac{1}{1 + e^{-\beta^T \mathbf{X}_i}}$$
 (sigmoid function)

■ For C = K > 2 (number of Class)

$$P(Y = l | \mathbf{X}_i) = \pi_l(\mathbf{X}_i) = \frac{e^{\beta_l^T \mathbf{X}_i}}{\sum_{c=1}^K e^{\beta_c^T \mathbf{X}_i}}$$
 (softmax function)

One-Vs-Rest

One-Vs-Rest

```
LogisticRegression(solver='sag', multi_class='multinomial')
'ovr'
```

Naïve Bayes Classifier

$$P(Y_i = k | \mathbf{X}_i) = \frac{P(\mathbf{X}_i | k) P(k)}{\sum_k P(\mathbf{X}_i | k) P(k)}$$

Bayes' Theorem

where
$$P(\mathbf{X}_i|k) = \prod_{j=1}^{p} P(X_{ij}|k)$$

LDA

$$P(Y_i = k | \mathbf{X}_i) = \frac{P(\mathbf{X}_i | k) P(k)}{\sum_k P(\mathbf{X}_i | k) P(k)}$$

Bayes' Theorem

where
$$P(\mathbf{X}_i|k) \sim N_p(\mathbf{\mu}_k, \Sigma)$$

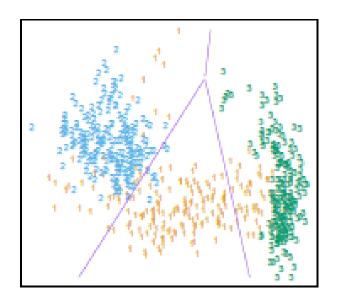

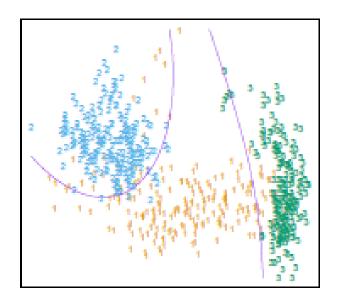

QDA

$$P(Y_i = k | \mathbf{X}_i) = \frac{P(\mathbf{X}_i | k) P(k)}{\sum_k P(\mathbf{X}_i | k) P(k)}$$

Bayes' Theorem

where
$$P(\mathbf{X}_i|k) \sim N_p(\mathbf{\mu}_k, \Sigma_k)$$

0-1 Loss

$$L[\tau(\theta), T(X)] = \sum I(Y_i \neq \hat{Y}_i)$$

The Bayes decision rule for minimizing the loss $(P(Y_i \neq \hat{Y}_i))$ is

$$\underset{k}{argmax} P(Y = k | \mathbf{X})$$

Loss function

$$L[\tau(\theta), T(X)] = L[Y, \hat{Y}]$$

Regression
$$\Rightarrow$$
 $L[Y, \hat{Y}] = \sum_{i=1}^{n} (Y_i - \hat{Y}_i)^2$

Classification
$$\Rightarrow$$
 $L[Y, \hat{Y}] = -\sum_{i}^{n} \sum_{k}^{C} Y_{i} \log \hat{\pi}_{i}(k)$

Machine "Learning"

$$\underset{\boldsymbol{\theta}}{\operatorname{argmin}} \ L[Y, \ \widehat{Y}] = \widehat{\boldsymbol{\theta}}$$

 \Rightarrow Optimization

Logistic Regression

$$L[Y, \hat{Y}] = -\sum_{i=1}^{n} [y_i \log \pi_i + (1 - y_i) \log (1 - \pi_i)]$$
$$= -\sum_{i=1}^{n} [y_i (\boldsymbol{\beta}^T \mathbf{X}_i) - \log (1 + \exp(\boldsymbol{\beta}^T \mathbf{X}_i))]$$

Logistic Regression

$$L[Y, \hat{Y}] = -\sum_{i=1}^{n} [y_i(\boldsymbol{\beta}^T \mathbf{X}_i) - \log(1 + \exp(\boldsymbol{\beta}^T \mathbf{X}_i))]$$

$$\widehat{\boldsymbol{\beta}} = \underset{\boldsymbol{\beta}}{\operatorname{argmin}} L[Y, \ \widehat{Y}]$$

⇒ Can you solve it?

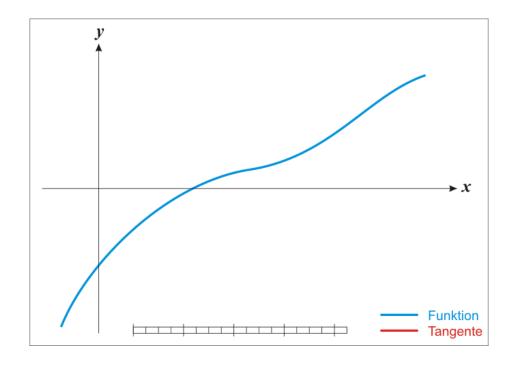

Optimization often can be rewritten as solving equations.

ex) Normal equation

 Some problems do not have an explicit solution and a numerical approach should be exploited.

Linear approximation (1st order Taylor Expansion)

$$f(x) \approx f(x_0) + f'(x_0)(x - x_0) = 0$$

$$x = x_0 - \frac{f(x_0)}{f'(x_0)}$$

$$\Rightarrow \theta^{(t+1)} = \theta^{(t)} - \frac{f(\theta^{(t)})}{f'(\theta^{(t)})}$$

- 1. Initialize $\theta^{(0)} = \theta_0$ which can be arbitrary on the domain of the function
- 2. Update for $t = 0, 1, 2, 3, \dots$

$$\theta^{(t+1)} = \theta^{(t)} - \frac{f(\theta^{(t)})}{f'(\theta^{(t)})}$$

until

$$\mid \theta^{(t+1)} - \theta^{(t)} \mid < \epsilon$$

for small $\epsilon > 0$

Quadratic approximation (2nd order Taylor Expansion)

$$f(x) \approx f(x_0) + f'(x_0)(x - x_0) + \frac{1}{2}f''(x_0)(x - x_0)^2$$

$$\frac{\partial}{\partial x}f(x) \approx f'(x_0) + f''(x_0)(x - x_0) = 0$$

$$x = x_0 - \frac{f'(x_0)}{f''(x_0)} \quad \Rightarrow \quad \theta^{(t+1)} = \theta^{(t)} - \frac{f'(\theta^{(t)})}{f''(\theta^{(t)})}$$

Quadratic approximation (2nd order Taylor Expansion)

$$L(\mathbf{\theta}) \approx L(\mathbf{\theta}_0) + L'(\mathbf{\theta}_0)^T (\mathbf{\theta} - \mathbf{\theta}_0) + \frac{1}{2} (\mathbf{\theta} - \mathbf{\theta}_0)^T L''(\mathbf{\theta}_0) (\mathbf{\theta} - \mathbf{\theta}_0)$$

Quadratic approximation (2nd order Taylor Expansion)

$$L(\mathbf{\theta}) \approx L(\mathbf{\theta}_0) + \nabla L(\mathbf{\theta}_0)^T (\mathbf{\theta} - \mathbf{\theta}_0) + \frac{1}{2} (\mathbf{\theta} - \mathbf{\theta}_0)^T \mathbf{H}(\mathbf{\theta}_0) (\mathbf{\theta} - \mathbf{\theta}_0)$$
where
$$\nabla L(\mathbf{\theta}_0) = \frac{\partial}{\partial \mathbf{\theta}} L(\mathbf{\theta}) \bigg|_{\mathbf{\theta} = \mathbf{\theta}_0}$$

$$\mathbf{H}(\mathbf{\theta}_0) = \frac{\partial^2}{\partial \mathbf{\theta} \partial \mathbf{\theta}^T} L(\mathbf{\theta}) \bigg|_{\mathbf{\theta} = \mathbf{\theta}_0}$$

Updating equation is

$$\mathbf{\theta}^{(t+1)} = \mathbf{\theta}^{(t)} - \mathbf{H}^{-1}(\mathbf{\theta}^{(t)}) \nabla L(\mathbf{\theta}^{(t)})$$
$$= \mathbf{\theta}^{(t)} - \mathbf{H}^{-1}(\mathbf{\theta}^{(t)}) \frac{\partial}{\partial \mathbf{\theta}^{(t)}} L(\mathbf{\theta}^{(t)})$$

$$cf. \ \theta^{(t+1)} = \theta^{(t)} - \frac{f'(\theta^{(t)})}{f''(\theta^{(t)})}$$

$$Loss[\boldsymbol{\beta}] = -\sum_{i=1}^{n} [y_i(\boldsymbol{\beta}^T \mathbf{X}_i) - \log(1 + \exp(\boldsymbol{\beta}^T \mathbf{X}_i))]$$

$$\nabla L(\mathbf{\beta}) = \frac{\partial}{\partial \mathbf{\beta}} L(\mathbf{\beta}) = -\sum_{i=1}^{n} \left[y_i \mathbf{X}_i - \frac{\exp(\mathbf{\beta}^T \mathbf{X}_i)}{1 + \exp(\mathbf{\beta}^T \mathbf{X}_i)} \mathbf{X}_i \right]$$

$$\mathbf{H}(\boldsymbol{\beta}) = \frac{\partial^2}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}^T} L(\boldsymbol{\beta}) = \sum_{i=1}^n \left[\left(\frac{\exp(\boldsymbol{\beta}^T \mathbf{X}_i)}{1 + \exp(\boldsymbol{\beta}^T \mathbf{X}_i)} \right) \left(\frac{1}{1 + \exp(\boldsymbol{\beta}^T \mathbf{X}_i)} \right) \mathbf{X}_i \mathbf{X}_i^T \right]$$

$$Loss[\boldsymbol{\beta}] = -\sum_{i=1}^{n} [y_i(\boldsymbol{\beta}^T \mathbf{X}_i) - \log(1 + \exp(\boldsymbol{\beta}^T \mathbf{X}_i))]$$

Update

$$\boldsymbol{\beta}^{(t+1)} = \boldsymbol{\beta}^{(t)} - \mathbf{H}^{-1} (\boldsymbol{\beta}^{(t)}) \nabla L(\boldsymbol{\beta}^{(t)})$$

until

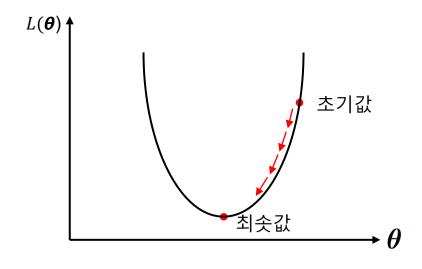

$$||\mathbf{\beta}^{t+1} - \mathbf{\beta}^t|| < \epsilon$$
 for small $\epsilon > 0$

 Newton-Raphson is expensive to compute due to the computation of the inverse of Hessian.

$$\mathbf{\theta}^{(t+1)} = \mathbf{\theta}^{(t)} - \mathbf{H}^{-1}(\mathbf{\theta}^{(t)}) \nabla L(\mathbf{\theta}^{(t)})$$

$$\Rightarrow \quad \mathbf{\theta}^{(t+1)} = \mathbf{\theta}^{(t)} - \eta^{(t)} \, \nabla L(\mathbf{\theta}^{(t)})$$

$$\mathbf{\theta}^{(t+1)} = \mathbf{\theta}^{(t)} - \eta^{(t)} \nabla L(\mathbf{\theta}^{(t)})$$

or

$$\mathbf{\theta}^{(t+1)} = \mathbf{\theta}^{(t)} - \eta \, \nabla L(\mathbf{\theta}^{(t)})$$

```
t0, t1 = 5, 50 # learning schedule hyperparameters

def learning_schedule(t):
    return t0 / (t + t1)
```

eta = learning_schedule(epoch * m + i) theta = theta - eta * gradients

Batch Gradient Descent

Regression → SSE

$$\nabla L(\mathbf{\beta}) = \frac{\partial}{\partial \mathbf{\beta}} L(\mathbf{\beta}) = -2\mathbf{X}^T (\mathbf{y} - \mathbf{X}\mathbf{\beta})$$

Logistic Regression → Cross Entropy

$$\nabla L(\mathbf{\beta}) = \frac{\partial}{\partial \mathbf{\beta}} L(\mathbf{\beta}) = -\sum_{i=1}^{n} \left[y_i \mathbf{X}_i - \frac{\exp(\mathbf{\beta}^T \mathbf{X}_i)}{1 + \exp(\mathbf{\beta}^T \mathbf{X}_i)} \mathbf{X}_i \right]$$

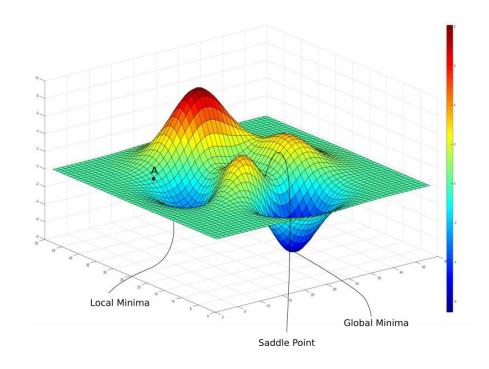

Steepest Descent

$$\boldsymbol{\theta}^{(t+1)} = \boldsymbol{\theta}^{(t)} - \eta \, \frac{\partial}{\partial \boldsymbol{\theta}^{(t)}} L(\boldsymbol{\theta}^{(t)}) \quad \Leftrightarrow \quad (\boldsymbol{\theta}^{(t+1)} - \boldsymbol{\theta}^{(t)}) \propto - \frac{\partial L(\boldsymbol{\theta}^{(t)})}{\partial \boldsymbol{\theta}^{(t)}}$$

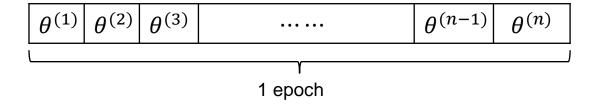

$$\frac{L(\boldsymbol{\theta}^{(t+1)})}{\partial \eta} = \left[\frac{\partial L(\boldsymbol{\theta}^{(t+1)})}{\partial \boldsymbol{\theta}^{(t+1)}}\right]^T \frac{\partial \boldsymbol{\theta}^{(t+1)}}{\partial \eta} = -\left[\frac{\partial L(\boldsymbol{\theta}^{(t+1)})}{\partial \boldsymbol{\theta}^{(t+1)}}\right]^T \frac{\partial L(\boldsymbol{\theta}^{(t)})}{\partial \boldsymbol{\theta}^{(t)}} = 0$$

 \Rightarrow $\theta^{(t+2)}$ and $\theta^{(t+1)}$ are orthogonal

Stochastic Gradient Descent

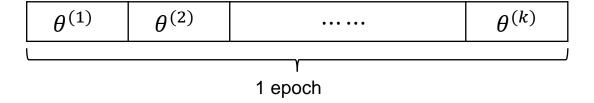

Stochastic Gradient Descent

Stochastic (Randomness) → Shuffle the data

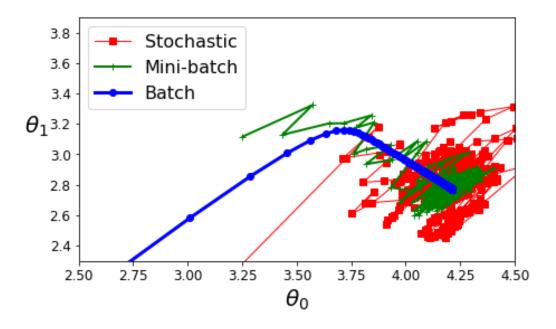

Stochastic Gradient Descent

Mini-Batch Gradient Descent

• k batches have p data \rightarrow n = k x p

Mini-Batch Gradient Descent

• What about $\eta^{(t)}$? \rightarrow in Deep Learning
